

Magic Squares

Science Or Magic?

Magic squares have been around for thousands of years and have fascinated so many with its unique construction of how numbers are arranged and put together.

Magic Squares in History

Magic squares have been studied for at least three thousand years, the earliest recorded appearance dating to about 2200 BC, in China. In the 9th century, Arab astrologers used them in calculating horoscopes, and by 1300 AD, magic squares had spread to the west. An engraving by the German artist Albrecht Durer includes a magic square in which the artist embedded the date 1514 in the form of two consecutive numbers in the bottom row! Because the concept of a magic square is so easily understood, magic squares have been particularly attractive to puzzlers and amateur mathematicians.

Construction of a Magic Square

Magic squares—a square arrangement of numbered squares containing rows and columns of numbers arranged in such a way that each horizontal, vertical, and diagonal line has the same sum. It consists of distinct positive integers. The magic comes from the fact that the numbers arranged in a square of equal sides all add the same total, coming and going, up and down, and often times even from an angle.

Types of Magic Squares

There are many types of magic squares. Some of these methods/forms include the construction of panmagic squares, Kronecker product, multiplicative magic squares, as well as the construction of a magic square using genetic algorithms. However, the simplest way is to follow certain arrangements that produce regular patterns. Magic squares can be classified into three types: odd, doubly even (n divisible by four), and singly even (n even, but not divisible by four). Odd and double even magic squares are more complex but several methods exist, including the LUX method for magic squares (due to John Horton Conway) and the strachey method for magic squares.
